The crystals of (I) are enantiomerically pure. However, due to the presence of any significant anomalous scatterers in the compound, the absolute configuration of the molecule has not been determined by the present X-ray diffraction experiment. The enantiomer used in the refinement was assumed to correspond with the configuration of the known chiral centres in a precursor molecule, which remained unchanged during the synthesis of (I).

There are two symmetry-independent molecules, A and B, in the asymmetric unit of (I), and these are depicted in Fig. 1. The corresponding bond lengths and angles for the independent molecules agree well with each other. Excluding the atoms of the p-fluorophenyl group, the core skeletons of the two molecules have the same absolute configuration and almost identical conformations, with only very minor differences in the puckering of some rings. The unweighted r.m.s. fit of the remaining non-H atoms of molecule A with the corresponding atoms of molecule B is 0.12 Å. The main difference between the conformations of the two molecules is the orientation of the plane of the p-fluorophenyl ring in molecule B, which is tilted by approximately 63° with respect to its orientation in molecule A. The angle between the mean planes through the p-fluorophenyl ring (excluding the F atom) and the pyrazole ring is 38.85 (11)° for molecule A and −23.86 (11)° for molecule B. Another difference between the two symmetry-independent molecules is that the positions of the lone electron pair and the H atom on atom N17 in molecule B are reversed with respect to their positions on atom N17A in molecule A. This effective inversion of the configuration at this N atom also has consequences for the hydrogen-bonding interactions, as described below.

In both independent molecules, the methyl groups C18 and C19 lie in the expected β orientation, while the geometry at the B/C and C/D ring junctions is in each case all-trans. The C4=C5 distances of 1.343 (3) and 1.346 (3) Å in molecules A and B, respectively, confirm the localization of the double bond at this position.

The cyclohexeneone ring A adopts a slightly distorted envelope conformation in both independent molecules, with
the distortion being more severe and slightly towards a half-chair conformation in molecule A. Atoms C1A and C1B form the envelope flap in the respective molecules and the conformation of this ring is a consequence of the C4=C5 alkene bond. The puckering parameters (Cremer & Pople, 1975) for this ring (atom sequence C1A–C5A/C10A) in molecule A are $Q = 0.436 (2) \, \text{Å}$, $q_2 = 0.347 (2) \, \text{Å}$, $q_3 = 0.265 (2) \, \text{Å}$, $\theta = 52.7 (3)^\circ$, and $\varphi_2 = 12.2 (4)^\circ$, while for molecule B (atom sequence C1B–C5B/C10B), $Q = 0.450 (2) \, \text{Å}$, $q_2 = 0.371 (2) \, \text{Å}$, $q_3 = 0.254 (2) \, \text{Å}$, $\theta = 55.7 (3)^\circ$, and $\varphi_2 = 8.2 (3)^\circ$.

The steroidal ring B exists in a slightly distorted chair conformation in both molecules, with puckering parameters for molecule A [molecule B in brackets] of $Q = 0.543 (2) \, \text{Å}$ [0.529 (2) Å], $q_2 = 0.099 (2) \, \text{Å}$ [0.082 (2) Å], $q_3 = 0.534 (2) \, \text{Å}$ [0.522 (2) Å], $\theta = 10.6 (2)^\circ$ [9.2 (2)$^\circ$] and $\varphi_2 = 195.1 (12)^\circ$ [192.7 (14)$^\circ$] for the atom sequence C5A–C10A [C5B–C10B].

Ring C has a chair conformation in both molecules, although it is slightly more distorted in molecule A than in molecule B. The puckering parameters for molecule A [molecule B in brackets] are $Q = 0.559 (2) \, \text{Å}$ [0.570 (2) Å], $q_2 = 0.077 (2) \, \text{Å}$ [0.041 (2) Å], $q_3 = 0.554 (2) \, \text{Å}$ [0.568 (2) Å], $\theta = 7.6 (2)^\circ$ [3.9 (2)$^\circ$] and $\varphi_2 = 218.0 (15)^\circ$ [207 (3)$^\circ$] for the atom sequence C8A/C9A/C11A–C14A [C8B/C9B/C11B–C14B]. The tetrahydropyridine ring D of the steroid nucleus adopts a half-chair conformation in both molecules A and B, twisted at C13A–C14A and C13B–C14B, respectively. The ring is considerably strained as a consequence of the presence of the fused planar pyrazole ring. The puckering parameters for ring D in molecule A [molecule B in brackets] are $Q = 0.497 (2) \, \text{Å}$ [0.480 (2) Å], $q_2 = 0.379 (2) \, \text{Å}$ [0.377 (2) Å], $q_3 = 0.323 (2) \, \text{Å}$ [0.297 (2) Å], $\theta = 49.6 (2)^\circ$ [51.8 (2)$^\circ$] and $\varphi_2 = 83.5 (3)^\circ$ [94.4 (3)$^\circ$] for the atom sequence N17A/C13A–C17A [N17B/C13B–C17B].

The pseudo-torsion angle C19A–C10A···C13A–C18A [–1.31 (15)$^\circ$] in molecule A and C19B–C10B···C13B–C18B [1.88 (17)$^\circ$] in molecule B provide a quantitative measure of the twist about the length of the molecule and show that the molecules in (I) are not twisted to any significant degree and, with the exception of the tilted p-fluorophenyl group, that the entire molecule is quite flat. The values are comparable with those of related structures (Thamotharan et al., 2003).

In (I), atom C24B forms a weak intramolecular C–H···N interaction (Table 1) with atom N17B of molecule B, which leads to a loop with a graph-set motif of S(6) (Bernstein et al., 1995). Atoms C27A and C27B are involved in weak intermolecular C–H···F interactions with atoms F26A and F26B, respectively, of two different adjacent molecules, and each interaction links the A and B molecules independently into chains which have graph-set motifs of C(4) and run parallel to the $y$ axis. Atoms N17A and N17B participate in intramolecular N–H···O or N–H···N hydrogen bonds with atoms O3B and N21A, respectively, of two different neighbouring molecules. These interactions serve to crosslink molecules A with B, and act co-operatively to produce chains of alternating A and B molecules which have a graph-set motif of $C_{2}(16)$ and run parallel to the $y$ axis. Atom C4A acts as donor for a weak intermolecular C–H···N interaction with atom N21B of an adjacent molecule.

**Figure 1**

A view of the two independent molecules of (I), showing the atom-labelling scheme. Displacement ellipsoids are drawn at the 30% probability level and H atoms are represented by spheres of arbitrary radii.
Experimental

A solution of 2′-(p-fluorophenyl)-17α-aza-D-homo-5-androsteno-
[17,16-c]-pyrazol-3β-ol (0.5 g, 1.186 mmol) in cyclohexanone (5 ml) and
toluene (100 ml) was distilled slowly while aluminium isoprop-
oxide (1 g) in toluene (10 ml) was added to remove moisture.
Distillation was continued for 30 min. The reaction mixture was
refluxed for 4 h and allowed to stand overnight. The solution was
filtered, the filtrate was steam distilled and the residue obtained was
crystallized from ethyl acetate to afford (I) (institution code DPJ-
255) (yield 0.35 g. 70.42%; m.p. 499–501 K).

Symmetry codes: (i) \( 2 - x, \frac{1}{2} + y, -z; \) (ii) \( x, y - 1, z; \) (iii) \( 1 - x, \frac{1}{2} + y, -z; \)

The positions of the amine H atoms were determined from a
difference Fourier map and refined freely along with their isotropic
displacement parameters. The methyl H atoms were constrained to
an ideal geometry (C—H = 0.98 Å), with \( U_{eq}(H) = 1.5U_{eq}(C) \),
but were allowed to rotate freely about the C—C bond. All remaining H
atoms were placed in geometrically idealized positions (C—H = 0.95–
1.00 Å) and were constrained to ride on their parent atoms. Due to
the absence of any significant anomalous scatterers in (I), attempts to
confirm the absolute structure by refinement of the Flack (1983)
parameter in the presence of 5710 sets of Friedel equivalents led to an
inconclusive value (Flack & Bernardinelli, 2000) of 0.2 (6). Therefore,
the Friedel pairs were merged before the final refinement and the
absolute configuration was assigned to correspond with that of the
known chiral centres in a precursor molecule, which remained
unchanged during the synthesis of (I). Reflections 003, T03, 012, 101,
110, 011, 002, T11, T02 and T01 were partially obscured by the beam
stop and were omitted.

Data collection: COLLECT (Nonius, 2000); cell refinement:
DENZO-SMN (Otwinowski & Minor, 1997); data reduction:
DENZO-SMN and SCALEPACK (Otwinowski & Minor, 1997);
program(s) used to solve structure: SIR92 (Altomare et al., 1994);
program(s) used to refine structure: SHELXL97 (Sheldrick, 1997);
molecular graphics: ORTEP-3 (Farrugia, 1997); software used to
prepare material for publication: SHELXL97 and PLATON (Spek,
2003).

RG thanks Panjab University for financial assistance and
Cipla Ltd, Mumbai, India, for the generous supply of the title
steroid.

Supplementary data for this paper are available from the IUCr electronic
archives (Reference: SK1692). Services for accessing these data are
described at the back of the journal.
